

APPARATUS AND METHOD FOR SIMULATED CAMPFIRE

FIELD OF THE INVENTION

5

The present invention broadly concerns camping and outdoor equipment. More particularly, the present invention is directed to portable campfires that generally can be used in any outdoor environment. Specifically, the present invention is directed a portable campfire apparatus and method that provides aesthetic pleasure while reducing risks to people and their environment. The present invention especially concerns a portable gas simulated campfire apparatus and method.

10

15

20

25

BACKGROUND OF THE INVENTION

In pre-historic times, humans depended on fire for survival. Fire provided light, warmth, protection from animals, and a means for cooking food. As a consequence of this reliance, humans also formed an intimate psychological connection with fire. Mysticism imparted certain spiritual and religious attributes to fire, gradually transforming the hearth into a place for social gathering. People congregated around open fires to interact with each other, dance, pray, and teach the new generation the history of the old. Arguably, these congregations helped to unify people and initiate the development of societies.

As time progressed, fire maintained a significant presence in the daily lives of people. Most homes were constructed with large fireplaces to serve as a source of light and heat, as well as a place to cook food. Humans discovered new and improved uses for fire. For

example, gas lamps allowed fire to be portable and light areas without the need of an open fire. Fire also became used for tool making, weapons, and other articles of manufacture. In modern times, fire is still used as a source of light, heat, and means for cooking food.

5 However, in general, its importance is diminished as compared to the past. Electricity has generally negated the need for fire as a source of light and open fires in fireplaces are typically not used as the primary source for heat or cooking. Generally, the modern home is furnished with electric or fuel heat, stoves, ovens, microwaves, and a variety of light fixtures.

10 For many people, the psychological bond with fire has endured all of these technological substitutes because they are generally enchanted by fire's esthetic qualities, its glow, its warmth, and even its smell. As a result, many homes continue to be constructed with fireplaces. Some homes have wood burning fireplaces while others are equipped with gas logs controlled by a remote on/off switch. In addition, many homes and dining tables are decorated with a variety of candles made of wax or decorative glass objects containing oils therein.

15 20 Fire is also present in the modern outdoor experience. Perhaps the most common of the modern outdoor experiences is cooking over an open flame on backyard barbecue grills. Oftentimes, backyard barbecues are associated with the gathering of friends and family for pleasurable occasions. Barbecue grills exist in a variety of forms including charcoal and gas grills. While some grills are permanently

25

DRAFT

affixed to an area, others are designed to be transportable for grilling at tailgate parties, campgrounds, and the like. Those that enjoy cooking outdoors in more remote locations value lightweight, compact camping stoves that are easily stowed in backpacks. These camping stoves are typically gas fired so that the backpacker is not required to also carry wood or charcoals on the trip.

5

10

15

20

25

In addition to cooking outdoors, many people still enjoy gathering around open fires. At parties, some people build outdoor fires in their backyards or along beaches. Usually these outdoor fires serve as one of the party's main attractions, alluring people to its warmth and light just as it did in the past. For others, open fires are enjoyed in national parks or other wilderness areas around the world. These fires are built either in designated pits or near chosen campsites and are sometimes a setting for campers to roast marshmallows and tell stories. Unfortunately, it has become increasingly dangerous for people to enjoy open fires outdoors, especially in national parks and wilderness areas. Persistent dry weather during the summer months create land very susceptible to uncontrollable fires that endanger lives, homes and even ancestral treasures. Prohibitions on outdoor fires are becoming commonplace in many national parks and wilderness areas.

Accordingly, there remains a need to provide a new design and construction for an open fire that greatly reduces the risk of causing uncontrollable fires, while at the same time, provides other attributes of an open fire. There is a further need to provide a design and construction for an open fire that is portable for those who enjoy fire in

national parks or other wilderness areas. The present invention is particularly directed to meeting these needs.

SUMMARY OF THE INVENTION

It is an object of the present invention to provide a new and useful campfire apparatus and method that is adapted to provide an open flame.

It is another object of the present invention to provide a camp stove and method adapted to create an open fire that is relatively free of embers.

A further object of the present invention is to provide a gas-fired camp stove that is portable yet provides an open flame in a relatively safe and convenient manner.

Yet another object of the present invention is to provide a camp stove that is gas powered to provide the appearance of open flames.

Yet another object of the present invention is to provide a camp stove that is easily manufactured and inexpensive in construction.

According to the present invention, then, a campfire apparatus is adapted to be placed in an assembled state on a support surface and connected to a source of fuel. Broadly, the campfire apparatus includes a base adapted to rest on the support surface when in an assembled state. A fire pan is adapted to be supported by the base when in the assembled state with the fire pan including a main body portion that has an inner surface, an upper rim and a pan interior. A gas manifold is then adapted to be disposed in the pan interior when in the assembled state. This gas manifold has at least one gas outlet

operative to introduce vaporized fuel into the interior of the fire pan when connected to the source of fuel. A quantity of low density, non-flammable particulate material is adapted to be disposed in the fire pan at a depth sufficient to cover the gas manifold when in the assembled state.

5

10

15

20

25

The particulate material should be sufficient so that the vaporized fuel migrates upwardly therethrough without igniting until it reaches the surface of the particulate material when connected to a source of fuel. To this end, campfire apparatus has a connector associated with the gas manifold that is adapted to connect to the source of fuel. The source of fuel is in the form of a reservoir that is portable, such as a propane tank. In any event, the particulate material is selected from a group consisting of particles of materials such as silicates, carbonates, coarse sands and certain ores. A preferred particulate material is vermiculite.

A lid may also be provided with this lid being sized and adapted to enclose the pan interior when placed thereon in a mounted state. A portion of the lid is thus supported by a portion of the main body of the fire pan. To this end, the fire pan can include an inwardly projecting shoulder disposed in surrounding relation on the upper rim with this shoulder portion operative to support the lid when the lid is in a mounted state.

Preferably, the base, the fire pan and the lid have generally the same geometrical configuration so as to reduce manufacturing costs. A spacer may also be provided with this spacer adapted to be

interposed between the fire pan and the base when in the assembled state so that the base supports the spacer and the spacer supports the fire pan. The base and the fire pan may be configured as a geometric shell selected from a group consisting of: a portion of a spherical shell, 5 a truncated pyramidal shell, a rectangular parallelepiped shell, a polyhedral shell, a conical shell, a cylindrical shell and a pyramidal shell. The lid may also have substantially the same geometric structure as the fire pan and the base. It is desired that the base and the fire pan be sized so that the plane of the upper rim is oriented parallel to the support surface when in an upright position but, when tipped over, the plane of the upper rim is oriented at no less than 90° to 10 the support surface so that the plane of the rim is oblique to the support surface. When assembled, it is desired that the fire pan, the base and the spacer have central axes that are co-linear. In assembly, one or more bolts interconnect the fire pan and the base with the spacer interposed therebetween. Here, bolts may extend between the base 15 and the fire pan through the hollow interior of the spacer.

The gas manifold of the present invention can take a variety of selected sizes and shapes. For example, the manifold may be 20 configured as in a toroidal, serpentine, linear or linearly angled shape. In some embodiments, the manifold is shaped so as to extend circumjacent to the inner surface of the fire pan when in the assembled state. The gas outlet is positioned to direct vaporized fuel laterally toward an axis that is perpendicular to the plane containing the rim of 25 the fire pan, that is, radially inwardly into the particulate material. The

gas outlet can be a single slit or channel extending around the manifold or, alternatively, can be a plurality of ports formed in spaced-apart relation to one another around the manifold thereby to define a plurality of gas outlets therefore.

5 The present invention is also directed to a method of providing an artificial camp fire on a support surface. This method includes a first step of providing a fire pan having an interior and wherein the fire pan includes a gas manifold disposed in the interior thereof with the manifold having at least one gas outlet operative to introduce vaporized fuel into the interior of the fire pan. Next, the fire pan is supported in spaced relation to the support surface such that the interior thereof is upwardly opening. The method includes the step of placing a quantity of low density, fire retardant particulate material in the fire pan at a depth sufficient to cover the gas manifold thereby to achieve a surface spaced completely above the gas manifold. The method then includes the step of introducing a fuel into the manifold at a pressure sufficient so that vaporized fuel is injected into the particulate material in a manner whereby the vaporized fuel migrates upwardly therethrough without igniting until it reaches the surface. The method then includes the step of igniting the vaporized fuel along the surface of the particulate material. The method may also include any step that is accomplished by the structure of the campfire apparatus described above.

10

15

DETAILED DESCRIPTION OF THE EXEMPLARY EMBODIMENTS

The present invention is directed to a portable campfire apparatus or camping stove that provides the aesthetic attributes of an open campfire that is relatively safe and convenient to use, even in situations where open fires may otherwise present a danger to humans or the environment. This campfire apparatus may connect to a source of fuel and provides a non-ember producing flame. Moreover, the construction design is such so that it can be produced at relatively reduced costs so that it may be quite affordable to the consumer.

10

15

20

With reference to Figure 1, the campfire apparatus 10 is shown connected to a fuel canister 12 by means of a conduit 14. Campfire 10 as shown, in Figure 1, in an operative apparatus wherein flames 15 are shown for representative purposes. Fuel canister 12 may be of any convenient type, but is preferably a propane canister having a valve 16 as is known in the art. Campfire apparatus 10, as well as fuel canister 12, is adapted to be placed in an upright position on a support surface 18 that may be any suitable surface, such as the ground, a patio, a deck or the like.

25

Campfire apparatus 10 is shown in greater detail in Figures 2-4. In these Figures, it may be seen that campfire apparatus 10 includes a

base 20, a fire pan 40, a lid 60 and a spacer 80. Base 20 is preferably in the form of an inverted frustum having a circular flat wall 22 and a side wall 24 that is formed of a conic sections that extends from flat wall 22 to terminate in an edge 26. A reinforcing channel 28 may be formed in side wall 24, if desired. Edge 26 is adapted to rest on the support surface 18 when in the assembled state, as is shown in Figure 2.

Fire pan 40 includes a main body portion 50 that is constructed substantially identically to base 20. Accordingly, fire pan 40 has a circular flat wall 42 and a side wall 44 formed as a conic section that terminates in an upper edge or rim 46. Reinforcing channel 48 again extends around a central portion of side wall 44. Flat wall 42 and side wall 44 thus form a frustum having an open interior 52 similar to open interior 32 of base 20.

When in the assembled state, spacer 80 is interposed between side walls 24 and 44 of base 20 and fire pan 40, respectively. To this end, spacer 80 has a cylindrical sidewall 84 and an open interior 82. Base 20 and fire pan 40 are releasably secured together by means of carriage bolts 36 and nuts 38 which extend through holes 34 and 54 formed, respectively, in flat walls 22 and 42. As noted, fire pan 44 is constructed substantially identically to base 20 except that fire pan 44 includes an opening 56 therethrough that is adapted to provide connection access for a manifold 90 discussed below. In addition, fire pan 40 has an annular shoulder portion 58 welded or otherwise formed at upper rim 46 with shoulder portion 58 extending continuously around

100-425-200-100

the fire pan 40 and being operative to support lid 60 thereon when the lid is in the mounted state.

Lid 60 is likewise formed substantially identically to base 20 and fire pan 40. Thus, as is best shown in Figure 3, lid 60 has a circular flat wall 62 and a side wall 64 formed as a conic section so that lid 60 is frustoconical in shape with an open lid interior 69. Side wall 64 extends from flat plate 62 to terminate in a rim 66. Reinforcing channel 68 may again be formed in side wall 64. Lid 60 sports a handle 70 that is secured to flat wall 62 by means of screws 74 extending through holes 76 into legs 78 of handle 70. Lid 60 is sized and adapted to enclose the pan interior when placed thereon in a mounted state with a portion of the lid being supported by shoulder portion 58.

Manifold 90 is best shown in Figures 3-5. Manifold 90 includes a toroidal main body 92 provided with a plurality of ports, such as ports 94, that form a plurality of gas outlets operative to introduce vaporized fuel into the pan interior 52 when connected to a source of fuel. To this end, toroidal main body 92 is hollow in cross-section and includes an extension 96 that may be disposed in and project out of hole 56 when campfire apparatus 10 is in the assembled state, as is shown in Figure 3. Extension 96 is provided with a connector 98 that is operative to connect to a source of fuel when in the assembled state in a manner that is standard in the art.

As is shown in Figure 5, the structure and orientation of ports 94 are such that the vaporized fuel is directed radially inwardly with main body portion 92 extending circumjacent the inner surface of fire pan 40

when in the assembled state. Thus, ports 94 direct the vaporized fuel laterally toward an axis that is perpendicular to the plane "P" containing rim 46 of fire pan 40. By being circumjacent, it is meant that the manifold extends proximately to the inner surface of side wall 44 of fire pan 40 when in the mounted state, as is shown in Figure 3.

An alternative gas manifold for the campfire apparatus 10 is shown in Figures 6 and 7. Here, gas manifold 100 is structured substantially identically to gas manifold 90 and includes a hollow, toroidal shaped main body 102 having an interior 103. An extension 106 is adapted to project through opening 56 in side wall 44 of fire pan 40. As is shown best in Figure 7, a slit 104 extends around the inner circumference of main body 102 to provide an outlet for vaporized fuel. Outwardly turned flanges 105 are in opposed facing relationship on either side of slit 104. Connector 108 is provided to attach to conduit 14 associated with fuel canister 12.

With reference to Figure 3, it may be seen that campfire apparatus 10 also includes a quantity of low density, non-flammable particulate material 30 that is disposed in the fire pan 44 at a depth "d" that is sufficient to cover gas manifold 90 when in the assembled state so that manifold 90 is completely engulfed in the particulate material.

Preferably, the particulate material 30 possesses a sufficient amount of porosity to create and maintain vapor channels through and/or between the particles that permit the passage of gas through the particulate material 30. Particles of materials such as silicates, carbonates, coarse sands and certain ores possess sufficient gas

5

porosity. More specifically, particles of clay, shale, slate, slag, zeolites, alumina hydrates, borates, perlite, vermiculite, beach sand, volcanic sand, sandblasting sand, and the like may be used. It should also be appreciated that certain types of silicates can be found both in an expanded or exfoliated form, as well as their crude or condensed form. This invention contemplates each of these various forms of silicates.

10

The preferred particulate material is vermiculite. Vermiculite is selected due to its property of permitting passage of the vaporized gas so that it migrates upwardly through the particulate material without igniting until it reaches surface 31 thereof. Moreover, vermiculite has been found to provide a matrix for the vaporized fuel that does not itself absorb heat or have a great thermal capacity. Thus, even when the fuel is ignited, the vermiculite material remains relatively cool to the touch. Moreover, the vermiculite does not produce embers that are discharged from campfire apparatus 10 when the fuel is ignited. Thus, there is a less potential for rogue fires resulting from embers being blown out of campfire apparatus 10. This is especially advantageous where the campfire apparatus 10 is used in a delicate, dry environment, such as a desert or arid camping area.

15

20

In addition, as is illustrated in Figure 8, another advantage of campfire apparatus 10 may be appreciated. Here, it may be seen that, by constructing base 20 and fire pan 40 substantially identically, with their central axes "C" aligned, the plane "P" of rim 46 of fire pan 40 is oriented at a perpendicular angle "a" with respect to the horizontal plane "H" when support surface 18 is horizontal and the campfire

25

5

apparatus is tipped over. Should campfire apparatus 10 be purposelessly or inadvertently placed in a tipped condition, as is shown in Figure 8, the vermiculite material 30 may spill out of fire pan 40 and remain in a fairly consolidated mass. It is also been found that, with the construction of campfire apparatus 10 as described with reference to Figure 1-5, the flame from manifold 90 will become extinguished. Thus, any open fire in fire pan 40 will be extinguished with the vermiculite 30 forming a non-threatening mass, that is, a mass that is not likely to inadvertently spread unwanted fire.

10

With reference to Figure 9, it may be noted that base 20' in this embodiment has an edge 26' that is smaller in diameter than rim 46 of fire pan 40'. Accordingly, plane "P" is oriented at an angle "a" with respect to the horizontal plane "H", that is, at an obtuse angle. Here again, the particulate mass 30 remains consolidated. Accordingly, it should be appreciated that, according to the present invention, a feature is having the rim of the fire pan 40 extend in a plane parallel to the support surface when in an upright position and, when in a tipped over position, the plane is oriented at no less than 90° to the support surface.

15

20

With reference now to Figures 10 and 11, a second alternative embodiment of the present invention is shown. Here, campfire apparatus 110 is square-shaped so that the base 120 and the fire pan 140 are each structured as a rectangular (square) parallel piped shell. Spacer 180 is again formed as a cylindrical shell. Serpentine manifold 190 is disposed in fire pan 140, near the square, flat wall 142 such that

25

DETAILED DESCRIPTION

it has a series of linear segments 191 extending side-to-side therein. Extension 196 of manifold 190 projects outwardly through opening 156 and is provided with a connector 198 to connect to a fuel source. A shoulder portion 158 projects upwardly and inwardly from rim 146 of fire pan 140 and is in the form of a truncated pyramid shell adapted to support the truncated pyramid-shape of lid 160. Lid 160 is again provided with a handle 170 to facilitate removal and placement on campfire apparatus 110. Vermiculite (not shown) should be employed to a depth sufficient to cover manifold 190.

A third exemplary embodiment of the present invention is shown in Figures 12-14. Here, camp stove or campfire apparatus 210 is formed to have an ovoid opening 211 formed by shoulder portion 258 extending from rim 246 of fire pan 240. Fire pan 240 and base 220 are formed as curvilinear shells with an oval or elliptical cross-section. Spacer 280 is in the form of an oval cross-section shell and is supported in base 220. Spacer 280 in turn supports fire pan 240, and a lid 260 is provided to rest on shoulder 258. Lid 260 is provided with handle 270 which may be configured as desired. A manifold 290 is placed in closely spaced relation to bottom wall 242 of fire pan 240 and is again in a serpentine configuration. Manifold 290 is again serpentine in configuration and it has arcuate sections 291 that extend adjacent to side wall 244 of fire pan 240 as well as linear sections 293 that extend lengthwise in fire pan 240. While the embodiment of campfire apparatus 210 is shown to have an oval opening, it should be appreciated that this opening could be circular without departing from

PCT/US2014/035242
PCT/US2014/035243
PCT/US2014/035244
PCT/US2014/035245
PCT/US2014/035246
PCT/US2014/035247
PCT/US2014/035248
PCT/US2014/035249

the scope of the invention. Thus, base 220, fire pan 240 and lid 260 could be formed as portions of a spherical shell, if desired.

Yet another exemplary embodiment of the present invention is shown in Figures 15-17. Here, campfire apparatus 310 has a triangular opening 311. Each of base 320, fire pan 340 and lid 360 are structured as truncated triangular pyramidal shells with fire pan 340 being supported by spacer 380 on base 320. As is shown in Figure 17, the pyramid shape of base 320, fire pan 340 and lid 360 is skewed so that side 315 can be placed against a support wall 318, if desired. 5
Manifold 390 is positioned in the interior of fire pan 340, similar to that described above and includes three legs 391 that are circumjacent side wall 344 of fire pan 340. Thus, manifold 390 is in the shape that is linearly angled. By this it is meant that the manifold is formed as linear sections wherein adjacent ones of the sections are oriented at an angle with respect to one another. An extension 396 of manifolds 390 projects outwardly of fire pan 340 and includes a gas connector 398, as 10
15
described above.

With reference now to Figures 19-20, another embodiment is shown wherein a campfire apparatus 410 includes a base 420, a fire pan 440 supported by a spacer 480 and a lid 460 for the fire pan 440. 20
Here, the structure is similar to that described above as to the other embodiments. However, campfire apparatus 410 has a non-square rectangular opening with each of base 420, fire pan 440 and lid 460 being formed as truncated rectangular pyramid shells. With reference 25
to Figure 20, it may be seen that manifold 490 is again a linearly

PCT/US2013/052000

angled shape adjacent linear sections 491 formed at an angle with respect to adjacent linear angled sections. Connector 498 is again provided to connect to a source of fuel.

Finally, with reference to Figures 21 and 22, yet another campfire apparatus 510 is shown. Campfire apparatus 510 is hexagonal in configuration so that base 520, fire pan 540 and lid 560 are each constructed as truncated pyramidal shells having a hexagonal base. Spacer 580 is interposed between base 520 and fire pan 540 so that fire pan 540 is supported by spacer 580 that is in turn supported on base 520. In Figure 22, it may be seen that the manifold 590 is in the form of a burner that is disposed adjacent to bottom wall 542. Manifold 590 has ports 594 that project radially outwardly so as to disperse vaporized fuel therefrom into the vermiculite mass (not shown) that is adapted to cover manifold 590. Again, a suitable extension tube 596 extends outwardly through opening 556 to interconnect manifold 590 and gas connector 598.

From the foregoing, it should be understood that the shape of the base, the fire pan and the lid of campfire apparatus of the present invention can take a variety of geometric configurations, all believed to be within the scope of the ordinarily skilled artisan having now read the above description. For example, this configuration may be a portion of a spherical shell or shell of other curvilinear configuration, a truncated pyramidal shell, a rectangular (or square) parallel piped shell, a polyhedron shell, a conical shell, a cylindrical shell or a pyramidal shell. Likewise, the configuration of the manifold may be selected as

appropriate and, again, is within the skill of the ordinary artisan having read this description. For example, the manifold may be a toroidal shape, a serpentine shape, a linear shape or a linearly angled shaped without departing from the scope of the present invention.

5 Further, from the above description, it should be appreciated that the present invention contemplates a method of providing a portable campfire on a support surface. This method includes any of the steps inherent in the above described apparatus. In particular, the method according to the present invention includes the step of providing a fire pan having an interior and wherein the interior and a gas manifold disposed in the interior. This manifold has at least one gas outlet operative to introduce vaporized fuel into the interior of the fire pan. The method also includes the step of supporting the fire pan in spaced relation to the support surface so that the interior of the fire pan is upwardly opening. Next, the method includes the step of placing a quantity of low density, fire retardant particulate material in the fire pan at a depth sufficient to cover the gas manifold thereby to achieve a surface space completely above the gas manifold. The method then includes the step of introducing a fuel into the manifold at a pressure sufficient so that vaporized fuel is injected into the particulate material in a manner whereby the vaporized fuel migrates upwardly therethrough without igniting until it reaches the surface of the particulate material. Finally, the method includes the step of igniting the vaporized fuel along the surface of the particulate material. In addition to these general steps, the method according to the present

10
15
20
25

invention includes the selection of particles of materials such as silicates, carbonates, coarse sand and certain ores. Preferably, the particulate material according to the method is vermiculite.

Accordingly, the present invention has been described with some degree of particularity directed to the exemplary embodiments of the present invention. It should be appreciated, though, that the present invention is defined by the following claims construed in light of the prior art so that modifications or changes may be made to the exemplary embodiment of the present invention without departing from the inventive concepts contained herein.

10
